APPENDIX MATERIAL FOR CHAPTER 1:
INTRODUCTION TO THE LATIN AMERICAN VOTER

By Ryan E. Carlin, Matthew M. Singer, and Elizabeth J. Zechmeister

In the text (page 17) we describe the programmaticness index that Kitschelt and Freeze (2010) develop based on the DALP project. Because this index may not be familiar to our readers, we explain it in more detail here and provide the components of that index for the reader. We are grateful to Kitschelt and Freeze for making their data available to us and we assume all responsibility for any errors in our description of their methods. We encourage the reader to read their paper and to go to the DALP website (https://web.duke.edu/democracy/) to see the codebook and to download the data.

Kitschelt and Freeze call their programmaticness index CoSalPo recognizing the 3 ingredients that they and others have identified as key to programmatic competition: cohesive positions within a party, issues being a salient part of parties’ appeals, and parties taking distinct positions from each other (operationalized as polarization). They measure each of these components for each issue area in the survey. Cohesion (Co) is the standard deviation of expert scores for each issue each party. Salience (Sal) is the percentage of valid answers from experts for each issue each party. Polarization (Po), as discussed in the text, is the mean distance of a focal party’s position on the issue from the positions of each of the other parties in the system, with each dyad’s distance weighted by the relative size of the two parties whose distance is being compared. The three components are then normalized between 0-1 and multiplied to create the CoSalPo scores for each issue by each party. The summary programmaticness measure (called cosalpo_4 in the DALP dataset) is constructed by averaging three of the five common issue scales (d1-d5) that have the highest CoSalPo scores, but no more than two of them may be economic and then one more question, either the highest scoring country-specific issue, or one of the remaining d1-d5 issue scores, provided the latter has a higher CoSalPo score than the customized national questions.

For the 18 Latin American countries, the issues in Table OA1.1 are included in the programmaticness score with the question wording below the table. All countries’ index scores include the question on tradeoffs between cultivating a national identity and accommodating minority rights and on attitudes toward traditional values. Then it includes at least one purely economic question and then the question from all others one the questionnaire with the highest programmaticness score. Table OA1.2 contains the components of the COSALPO index for each country.
Table OA1.1: Dimensions Included in the COSALPO Index for Each Country

The following two questions are included in all measures of the index:

*National identity* [1] Party advocates toleration and social and political equality for minority ethnic, linguistic, religious, and racial groups and opposes state policies that require the assimilation of such groups to the majority national culture. [10] Party believes that the defense and promotion of the majority national identity and culture at the expense of minority representation are important goals.

*Traditional authority, institutions, and customs* [1] Party advocates full individual freedom from state interference into any issues related to religion, marriage, sexuality, occupation, family life, and social conduct in general. [10] Party advocates state-enforced compliance of individuals with traditional authorities and values on issues related to religion, marriage, sexuality, occupation, family life and social conduct in general.

The index also includes at least one of the following three economic issue questions:

*Social spending on the disadvantaged* [1] Party advocates extensive social spending redistributing income to benefit the less well-off in society. [10] Party opposes extensive social spending redistributing income to benefit the less well-off in society.

*State role in governing the economy* [1] Party supports a major role for the state in regulating private economic activity to achieve social goals, in directing development, and/or maintaining control over key services. [10] Party advocates a minimal role for the state in governing or directing economic activity or development.

*Public spending* [1] Party supports extensive public provision of benefits such as earnings-related pension benefits, comprehensive national health care, and basic primary and secondary schools for everyone. [10] Party opposes an extensive state role in providing such benefits and believes that such things as health insurance, pensions, and schooling should be privately provided or that participation in public social insurance programs should be voluntary.

Finally, the survey included a large battery of questions on other issues. Kitschelt and Freeze identified the one which had the largest programmatic score. The following questions make that list in at least one country.

Taxes vs. Social policies [1] Party supports lower taxes at the expense of social policies. [10] Party supports social policies, even when this leads to higher taxes.

APPENDIX MATERIAL FOR CHAPTER 2:
WHO IS THE LATIN AMERICAN VOTER?
By Ryan E. Carlin and Gregory J. Love

As referenced in footnote 12, Figure OA2.1 summarizes the model fit for each block of the turnout model for each country in the sample.

Figure OA2.1 Distribution of Model Fit by Country

Countries with enforced compulsory voting.
Countries with high party system polarization (< 1 std. dev. above mean).
APPENDIX MATERIAL FOR CHAPTER 3:
THE LEFT AND MOBILIZATION OF CLASS VOTING IN LATIN AMERICA
By Scott Mainwaring, Mariano Torcal, and Nicolás M. Somma

As referenced on page 74, online appendix table OA3.1 shows the distribution of the mean household wealth variable by country.

</table>

Note: The country means for household wealth and the number of survey respondents include individuals who were not categorized by our revamped Erikson-Goldthorpe class. Because by definition the mean household wealth for all individuals in the region equals exactly 0 for each year, improvements for the region as a whole are not registered. The number of observations is for the 2008 survey for Argentina and Panama; there was no survey in Argentina in 2006, and we found some minor problems in the original data for household wealth for Panama 2006.

Source for mean household wealth: AmericasBarometer 2006.
As referenced on page 75, Appendix Table OA3.2 shows the statistically significant (p<.10, two-tailed) results for the 2006, 2008, and 2010 AmericasBarometer surveys, using only the survey that immediately followed a given presidential election.\(^1\) Although we included all candidates in the regressions, to save space and focus attention on the most important results, we list only the candidates who obtained at least 10% of the valid vote according to survey responses. The “Change in probabilities” column is based on simulations produced from the estimated models. It shows the percentage change in the probability that a very wealthy respondent compared to a very poor respondent (as we shift from the lowest to the highest value for household wealth in a given country) would vote for a given candidate as opposed to the conservative reference candidate. A positive value indicates that wealthier voters were more likely than poor voters to prefer the more progressive candidate after controlling for age, sex, and size of the city of residence. A negative value shows that wealthy individuals were less likely than poor voters to support the more progressive of the two candidates.

\(^1\) Argentina and Venezuela were not part of the 2006 survey. We did not include Panama 2006 because of some minor problems with the variables used to create our household wealth variable or Bolivia 2006 because the question about population size where the respondent lives was not asked.

Source: AmericasBarometer 2006-2010.

Note: The total N includes all candidates including those not shown in Table A2; therefore, the total N is greater than the sum for the candidates shown in Table A2. The weighted average change includes only candidates shown in Table A2; it excludes minor candidates.
Table OA3.3 synthetically summarizes results for legislative voting in the same manner as Table 3.1 for presidential voting. The data come from the 2006 AmericasBarometer, the most recent year for which it asks about congressional voting. The survey question is “For which party did you vote for deputy in the last elections.” The final column arrays the nine countries from strongest to weakest class voting based on the weighted change in voting probabilities from the poorest to the wealthiest voters. The summary scores for these nine countries are extremely highly correlated \((r = .97)\) with their scores in Table 3.1, showing great consistency in the results for presidential and legislative voting. There is again great variance across countries.

Source: AmericasBarometer 2006 survey.

In three comparisons including the two with the greatest change in probabilities, wealthy voters were more likely than the poor to support the more progressive party (i.e., reverse class voting). Consistent with our finding for the 2004 presidential election, the most
A surprising result is that in El Salvador wealthier voters reported that they were more likely than poor voters (+27%) to support the leftist FMLN over the conservative ARENA. Also consistent with the findings for presidential elections, in Costa Rica, wealthier voters were much more likely (+31%) than poor voters to prefer the center-left Citizen Action Party over the centrist National Liberation Party in 2006. Finally, in Nicaragua, wealthier voters were relatively more likely than poor voters (+10%) to choose the leftist FSLN over the conservative PLC. Given the hostile relationship between business groups and the FSLN when it governed from 1979 to 1990, this finding is surprising. Ten paired comparisons of parties were statistically insignificant.

Moving to our second measure of class voting, Table OA3.4 shows the results for the Erikson-Goldthorpe schema for presidential candidates for whom at least 10% of survey respondents voted according to the survey. The six class variables are dummy variables. The reference class category in all comparisons is the petty bourgeoisie, traditionally seen as a class with conservative political preferences. We do not show results for the control variables and show only the statistically significant results (p<.10). We do not show results for Costa Rica (2006), the Dominican Republic (2006), Ecuador (2008 and 2010), El Salvador (2006), Honduras (2006), and Panama (2008) because none of the class coefficients was statistically significant.

A negative sign in the class cells indicates that a given class was disproportionately favorable to the more conservative (i.e., the reference) candidate. A positive sign means that the class voted disproportionately for the less conservative candidate. The number shows the change in the likelihood that a given class would vote for one candidate over another, relative to voting among the petty bourgeoisie. For example, in Argentina, controlling for age, sex, and residence size, unskilled workers were 27% more likely than the petty bourgeoisie to vote for Cristina Fernández de Kirchner rather than Roberto Lavagna, among unskilled workers and
petty bourgeois who voted for one of these two candidates.

On page 86 the text references a Table OA 3.5; that is a typographical error and the data are compiled based on the results in Table OA 3.4. We apologize for the mistake.

As discussed on page 237, Figure OA9.1 shows how partisanship structures political participation in Latin America.

**Figure OA9.1. Mass partisanship and political participation in Latin America**

*Notes:* Mass partisanship and political participation in Latin America. Values represent changes in the predicted probability that a respondent engages in each type of political participation, based on shifting each variable from its sample 25th to 75th percentile, with all other continuous variables held at their sample means and ordered variables held at their sample medians. Solid lines show the simulated 95 percent confidence interval. Black dots represent values that are significant at 95 percent confidence, white dots those that fall short of that threshold. These predicted values are based on the estimates from multilevel probit models available from author.

APPENDIX MATERIAL FOR CHAPTER 10:
CLIENTELISM IN LATIN AMERICA: EFFORT AND EFFECTIVENESS

By Herbert Kitschelt and Melina Altamirano

1. Determinants of clientelistic targeting at the individual level

To explore the determinants of clientelistic targeting at the individual level as discussed on page 258, we estimate a logit model drawing upon the 2010 AmericasBarometer survey. The dependent variable is the vote-buying item in the survey, asking respondents whether they have been offered material goods in return for their vote. The model includes country fixed effects and observations are weighted. The reported independent variables intend to capture the targeting criteria discussed above. Figure 10A.1 below displays the mean and 95% confidence interval of the parameter estimates in the model.

Figure OA10.1: Correlates of Being Offered Something in Exchange for your Vote, 2010 AmericasBarometer.

Results are generally consistent with the arguments in the literature and the patterns emerging from the DALP data on party strategies. Respondents’ household wealth has a negative and significant effect on the likelihood of being targeted with clientelistic offers. In contrast, individuals living in rural communities are more likely to be offered material benefits in exchange of their vote. Interestingly, those respondents who participate more actively in partisan organizations are more likely to report experiences related to vote-
buying attempts. This finding resonates with arguments emphasizing political networks as mechanisms determining preferential access to certain goods, thus conditioning voters’ expectations. Women and older people tend to report less experience with clientelistic practices, while education does not seem to have a significant effect on targeting. Individuals self-identifying as indigenous are no more likely to report vote-buying attempts in our model. But this effect might vary by country depending on the political salience of ethnic cleavages.

2. Robustness checks: Experts' judgment and ideological closeness

Table OA10.1 presents several robustness checks to the models in Table 10.1. The specific robustness tests are discussed on page 262 and include the introduction of controls for the level of confidence of experts in their own judgment of the parties and their level of ideological closeness to a given party.

2 The exact wording of this question is: I am going to read a list of groups and organizations. Please tell me if you attend their meetings at least once a week, once or twice a month, once or twice a year, or never: Meetings of a political party or political organization? The scale was inverted so that higher values reflect more participation.
3. Mechanisms for party-level controls

As discussed on page 262, we include several party-level variables that are not the central interest of this chapter but which help explain variation across parties. Space constraints did not permit the full discussion of those mechanisms in the paper, so we outline their logic here.

1. One possibility is the construction of a vast formal party organization with offices and agents in every village and neighborhood that are embedded in the local setting and can monitor locals through informal and unobtrusive means.

2. Politicians may also rely on more informal networks of local notables situated at the intersection of community communications networks (e.g. teachers or pastors, barbers or general store owners, pawn shopkeepers and local bankers...). These notables are not necessarily card-carrying party members, but may socially feed into the entourage of elected politicians, communicate demands from the electoral constituency, and in return may assist politicians to mobilize support.

3. Politicians may also draw on key operatives in an infrastructure of civic self-organizations, configured around associations of business, labor, religion and churches, ethnic, women and neighborhood groups. If they have close contact to representatives of such networks, and are receptive to their concerns, politicians may “delegate” the task of mobilizing support and compliance with clientelistic exchange without having to build their own organizations.
4. Regardless of which organizational capabilities politicians rely on, they have **to put these capabilities to goal-oriented use.** It takes political will and skill, not just resources, as the proximate effective cause to hold the opportunism of clients at bay. We may therefore want to check the **direct effect of client monitoring,** in addition to, or in interaction with associational capabilities to restrict voter opportunism. Nevertheless, it should be clear that even the most skilled politicians cannot possibly mobilize the resources to stop the bucket of clientelism from leaking entirely.

5. Next, whether or not clientelistic inducements are effective or not may **depend on properties of the target voters.** Voters may be more or less receptive to clientelistic inducements, and they may feel closer or more distant from the party. Voters close to a party (“loyalists”) may choose between turning out for “their” party or staying home otherwise. So clientelism may be aimed primarily and in the short run at turnout buying (Nichter 2008). But voters may also be indifferent between several parties on other grounds than clientelistic inducements, more likely because they have no policy preferences and/or cannot discern between parties’ policy appeals (or discount their credibility), and more rarely because voters’ ideology places them between parties (“strategists”).

6. Following up on this previous point, the final possibility is that if parties also adopt **programmatic policy appeals** with large-scale club and collective goods positions, their remaining efforts to provide clientelistic benefits may become electorally less effective. They may still serve some elements of their electoral support coalitions through clientelistic means, but the significance of this effort in the “linkage mix” of parties is modest. Hence politicians may tolerate some comparatively ineffective mechanisms to reach out to citizens. We conceive the dampening effect of programmatic effort on clientelistic effectiveness more as a control than as an intrinsically and theoretically interesting insight.

---

3 Is it more efficient to pay off “strategists” or “loyalists” with clientelistic benefits? The literature has taken rival views on this question (with the classics being Cox and McCubbins 1986; Dixit and Londregan 1996, although in both instances the alternatives do not quite capture the precise meaning of clientelism, as employed here). Of course, whether parties better pay off one or the other target group may be itself contingent upon partisan capabilities of coordination and communication, not just persuasion of voters (Cox 2009). And under some conditions it may be best for parties to differentiate their efforts across a range of political channels (Magaloni et al, 2007).
APPENDIX MATERIAL FOR CHAPTER 12:
THE VARYING TOLL OF CORRUPTION PERCEPTIONS ON PRO-INCUMBENT VOTE CHOICE IN LATIN AMERICA

By Luigi Manzetti and Guillermo Rosas

The full specification of the multilevel logit model in Table 12.2 is captured in the following statements:

\[
\frac{\pi_i}{1 - \pi_i} = a_{i[j]} + \beta^0 X_{i}^{0} + \beta^1 j X_{i}^{1} + \text{Corruption Perception}_{i}
\]

\[
\beta^1 j \sim N(0, s_{\beta^1 j}^2)
\]

\[
\beta^0 j \sim N(Z_j, s_{\beta^0 j}^2)
\]

\[
\beta^1 j \sim N(Z_j, s_{\beta^1 j}^2)
\]

In these statements, \(\pi_i\) is the probability that citizen \(i\) will vote for the incumbent. We divide individual-level predictors in two sets. In the first set, we include predictors \(X^0\) for which we estimate pooled effects that are not allowed to vary across surveys \(\beta^0\). The second set includes predictors \(X^1\) for which we estimate random slope coefficients \(\beta^1 j\). These include the pro- and anti-incumbent behavior of voters in the previous election, as well as income and bureaucratic bribery. The distribution of these random coefficients is assumed normal, with variance parameters estimated from the data. Finally, we include modeled random coefficients \(\alpha_j\) and \(\theta_j\) for the intercept and the effects of corruption perceptions. The model for these parameters includes a number of predictors observed at the survey level (\(Z\)), as can be seen in the last two statements above. Among these predictors, we incorporate survey-level averages of all the individual-level variables in order to prevent heterogeneity bias (Mundlak 1978, Bartels 2008, Bafumi and Gelman 2010, Bell and Jones 2012). More importantly, we consider at the survey-level the potential effect of several contextual variables. We include these contextual variables one at a time in alternative specifications. The models are estimated via restricted maximum likelihood using the lmer package in R.

The tables that follow include data on the number of observations in the ordered logit models of what leads people to say their government is corrupt, the country-specific results about what factors are correlated with assessments of government corruption (Figure OA12.1) and personal corruption victimization (Figure OA12.2) as discussed on pages 303-305 and 305-306, and the results of the multi-level models summarized in Table 12.2 (Table OA12.2 and OA12.3).

APPENDIX MATERIAL FOR CONCLUSION

By Ryan E. Carlin, Matthew M. Singer, and Elizabeth J. Zechmeister

The appendix to chapter 14 contains three pooled models of vote choice across the hemisphere, each summarized graphically as a figure. Tables OA14.1, OA14.2, OA14.3, OA14.4, and OA14.5 present the full results of those models along with the country-specific fixed effects.

REPLICATION FILES

We have worked to provide replication files for interested readers who wish to extend the analyses in this volume. Readers can download a zip folder “Latin American Voter Replication Files” from the book’s website (https://www.press.umich.edu/8402589/latin_american_voter) which contains all the replication files we received from the authors. This folder contains the do files and, in some cases, ancillary data to replicate the analyses in "The Latin American Voter." In most cases the survey data itself is not deposited but should be downloaded from the original sources. The replication files were provided by the authors and have not been independently checked by the editors. If issues arise in using the data, we encourage the interested reader to contact the authors directly for further information. We also ask that work which uses the replication files cite the original chapter and be shared with the authors of that chapter as well as the editors of the volume for our information.
